DETERMINATION OF POSSIBLE INTERFERENT COMPOUNDS TO THE DETECTION AND MONITORING SYSTEM FOR THE QL PRODUCTION FACILITY

I. INTRODUCTION

The proposed detection and monitoring system for the Bigeye QL* production facility consists of using the MIRAN/1B and MIRAN 80 infrared (IR) analyzers supplemented by the Hydrogen Flame Emission Detector (HYFED) PA260 phosphorus analyzer. Basically, the IR analyzers would be calibrated at selected wavelengths to detect the leakage of compounds at designated sites throughout the facility. At these wavelengths, the target compounds QL, KB, and YL would be detected. However, other compounds used at the facility may absorb at some of these selected wavelengths. These interferent compounds must be identified to minimize the frequency of false alarms of the detection system. The PA260 analyzer would be used to detect only the organophosphates, QL, and YL. Although this analyzer responds to all phosphorus compounds, it will be used in conjunction with the MIRAN analyzers to provide a complete detection system,

The selection of the monitoring wavelengths is extremely critical in achieving a monitoring system with reliable detection capabilities for target compounds while minimizing false responses due to interferent compounds. Therefore, it would be necessary to obtain an IR spectrum of all of the compounds (identified in Table 1) used in the QL production process. The commpounds used in the QL production process would also include any construction materials (i.e., paints, primers, cleaning solvents, etc.) that are used in fabricating the munition and shipping containers. A list of these compounds is shown in Table 1. The resulting spectra would then be compared with the monitoring wavelengths to determine the degree of interference.

2. EXPERIMENTAL PROCEDURES

Whenever possible, the IR spectrum of a compound was obtained through commercially available or in-house libraries. The spectrum for compounds that do not exist in any library were obtained through analysis on a DIGILAB Model FTS-20-E/D Fourier Transform Infrared Spectrometer (FTIR) interfaced to a Hewlett-Packard Model 5880 Gas Chromatograph. A fused silica megabore column (30 m by 0.53 mm) with a 1.5- μ m thick liquid phase of 95% dimethyl-(5%) diphenylpolysiloxane was used in all separations.

Compounds were analyzed neat whenever possible. Some samples such as paints, primers, solvents, and the degradation products of QL samples were analyzed as shown in the following sections.

2.1 Paints and Primers.

Approximately 4 mL of paint or primer sample was placed in a test tube and centrifuged at 2500 rpm for 1.5 hr to remove pigments. The supernatent was removed and analyzed (neat or mixed 50:50 with acetone) under the following conditions:

^{*}All chemical names are identified in Table 1.

- Temperature Program: 50 °C for 2.5 min, then 8 °C/min to 240 °C
- Carrier Type: Helium at 8 cm³/min
- Sample Size: 0.7 µL

2.2 Solvents.

Both solvents (Nature Sol 100 and Nature Sol Emulsion) were analyzed neat under the following conditions:

- Temperature Program: 120 °C Isothermal
- Carrier Type: Helium at 10 cm³/min
- Sample Size: 1 µL

2.3 Degradation Products in QL Sample.

A degraded QL sample was analyzed neat under the following conditions.

- Temperature Program: 80 °C for 1 min, then 12 °C/min to 240 °C
- Carrier Type: Helium at 10 cm³/min
- Sample Size: 1 uL

For all analyses, the temperature of the light pipe was maintained at 250 °C; light pipe make-up flow was 6 cm 3 /min, and light pipe vent was 0.5 cm 3 /min.

Operation of the PA260 was reported earlier.*

RESULTS AND DISCUSSION

The target compounds to be monitored at the QL production facility are QL, YL, and KE. Table 2 lists the preliminary monitoring wavelengths for these compounds on the MIRAN analyzers. The IR spectrum of every compound used in the QL production process was examined for IR absorption at these particular wavelengths, and the results are summarized in Table 3. Many of the compounds tested show IR absorbance at one of the selected wavelengths. Seven compounds (TEP, TEPO, HAC, LT, MD, MPA, and trisodium phosphate) absorbed at two of the wavelegths.

Some of the chemicals used in the QL process, which are not commercially available, are still in the process of being obtained. Many of these compounds structures are very similar to compounds in which IR spectra have already been obtained. For example, MR, MP, and ML are identical in structure to TR, TEP, and QL, respectively, except for the presence of a methoxy group

^{*}Ferguson R.E., Ellzy, M.W., Lovrich, J., Stozzle, T., Janes, L.G., and Lindsay, T.J., U.S. Army Chemical Research, Development and Engineering Center, July 1988, unpublished data.

(OCH₃) instead of an ethoxy group (OC₂H₅). Similarly, TRX is identical to TRO in structure except TRX has an ethyl group instead of an ethoxy group. Such small differences in structure may not effect the IR spectrum enough to warrant their synthesis. It may be possible to determine their interference from already obtained spectra. In addition, the possible interference of some of the hyphenated compounds, MR-YL for example, may be inferred from the spectra of their individual componets (MR and YL). Each of these compounds is being examined for properties and possible methods of synthesis due to its relationship to the other compounds investigated.

Table 4 lists the basic components of the paints, primers, and solvents used at the QL production facility and their possible interference at the selected wavelengths.

3.1 Paints and Primers.

Many of the individual components found in the paint and primer samples interfered at one of the selected wavelenghts. Acetone and methyl ethyl ketone absorbed at two of the selected wavelengths. Both of these compounds have high vapor pressures and are typically found in high concentrations in many paints and primers. Some of the minor components in Primer TT-P-664 could not be positively identified but showed no absorption in the areas of interest. In addition, many compounds with halogen moiety (i.e., methylene chloride) or substituted benzene compound (toluene or xylene) may interfere at the QL wavelength.

3.2 Solvents.

There were only two major components found in the solvents, dipropylene glycol methyl ether and limonene. One solvent seems to be a watered down version of the other. The ether absorbed at the KB wavelength. Limonene, which gives the solvents their citrus odor, did not absorb at any of the wavelengths.

Any compound that absorbed at any of the selected wavelengths could be a possible interferent to the detection system. However, the compound's concentration and strength of IR absorbance at the selected wavelength will greatly determine whether the presence of the compound will initiate a false alarm. The MIRAN analyzer's MDL is, on the average, 0.5 ppm and will respond to any compound that absorbs IR radiation at a given wavelength. Because of this, a test of all of the possible interferences on the MIRAN analyzer may not be useful.

The PA260 phosphorus analyzer will respond to any phosphorus-containing compounds used at the QL facility in concentrations down to 0.5 ppb or less. In theory, the PA260 response should be directly related to the amount of phosphorus present in the molecule. The response should be twice as much for a compound with two phosphorus atoms than for a compound with one phosphorus atom at the same concentration. However, there are small differences in the PA260 response between different organophosphates with the same number of phosphorus atoms per molecule. For example, the Figure shows the PA260 response to QL, YL, TEPO, and TR. The response is slightly different for each compound tested, resulting in a family of linear calibration curves. However, at any given response to the PA260, equivalent concentrations for

QL, YL, TEPO, and TR could easily be determined from such a group of calibration curves. Therefore, a PA260 response of 5 x 10^{-9} amps would result in concentrations of 0.028 mg/m 3 , 0.140 m/m 3 , 0.024 mg/m 3 , and 0.008 mg/m 3 for QL, YL, TEPO, and TR, respectively.

4. CONCLUSIONS

Over 88% of the compounds in the QL production process have been analyzed for IR absorption at the selected wavelengths. The remaining compounds are in the process of synthesis or being obtained through commercial sources. All construction materials (i.e., paints, primer, and solvents) have been analyzed. Many of the compounds absorbed at one or two of the selected wavelengths.

The PA26C analyzer will respond to any phosphorus compound at a concentration level of 0.5 ppb or better. Some differences have been observed in calibration curves when challenging the PA26O with QL, YL, TEPO, and TR. Equivalent concentrations for these or other organophosphate compounds can be determined for any given response of an individual PA26O analyzer.
